## ABSTRACT

Airbnb has become more and more popular under the trend of sharing economy. In order to attract new users to place their first booking on Airbnb and offer a more personalized experience, we aim to build a recommendation system by using collaborative filtering approach, to predict which country these new users will make their first booking. Also the hosting data for various countries will be analyzed to provide better insight around booking area.

## Keywords

Learning Algorithms; Recommendation Systems; Collaborative Filtering; Cluster Models

## 1. INTRODUCTION

Data mining is the process of discovering interesting patterns from massive amounts of data. As a knowledge discovery process, it typically involves data cleaning, data integration, data selection, data transformation, pattern discovery, pattern evaluation, and knowledge presentation [1]. The science of learning plays a key role in the fields of data mining, statistics and artificial intelligence, intersecting with areas of engineering and other disciplines[2]. In a typical scenario, a quantitative or categorical outcome measurement is predicted based on a set of features.

Recommendation algorithms are a kind of learning algorithms which are widely used on e-commerce web sites. they use input about a customer's interests to generate a list of recommended items. Most recommendation algorithms are designed for finding similar customers, where they aggregate items from the similar customers, eliminates items the user has already purchased or rated, and recommends the remaining items to the user. The popular versions of these algorithms are collaborative filtering and cluster models. In the collaborative filtering, the similarity of customers is measured by the cosine of the angle between the two vectors which represent users' interests[3]. Using this algorithm to generate recommendations is computationally ex-

pensive, but it can be released by dimensionally reduction techniques[4]. To find the similar customers to the user, cluster models divide the customer base into many segments and treat the task as a classification problem[5]. Some algorithms classify users into multiple segments and describe the strength of each relationship[6]. Besides grouping the user to the similar customers, other algorithms such as search-based methods and item-to-item collaborative filtering focus on finding similar items[7]. Search- or content-based methods treat the recommendations problem as a search for related items[8].

User experience is now a critical factor to keep users and attract new users among web applications. That is the reason Airbnb wants to provide personalized and unique experience for its new users, thus Airbnb need an effective recommendation system to recommend a country for first-time booking.

However, the main challenge here is that Airbnb doesn't have the travel history or other type of the traveling data of new users, the only data available here is basic feature such as age, gender, session log etc., basically like a white paper to a recommendation system. While a typical recommendation system might make recommendation based on a few strongly related features, the system designed here need to focus on correctly classify similar users first, then trying to make recommendation with some relatively strong features. And that is why we choose collaborative filtering as our first-step approach.

## 2. DATASET DESCRIPTION

The training data consists of 213451 rows and 16 columns, while test user set has 62096 rows and 15 columns. The additional column is a 'country\_destination column', and this is where our predictions will be focused on.

About 60% of the users did not making a making (NDF:no destination found). US is the most popular destination among who booked a travel destination.

Quite a few age values are given in the year format. For now we ignore the null values and inconsistent values, and the corrected data will be presented in the next update.

Compared to basic sign-up and Facebook sign up users, those who signed up via Google have a much lower tendency to book a trip to U.S.

The differences between genders on destination country choices are not significant. It might be hard to generate any useful conclusion based on gender.

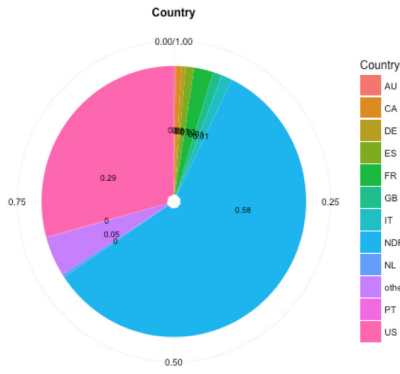

Figure 1: Destination Country Distribution.

Table 1: User Age Statistics

|              |        |
|--------------|--------|
| Minimum      | 1.00   |
| 1st Quartile | 28.00  |
| Median       | 34.00  |
| Mean         | 37.41  |
| 3rd Quartile | 43.00  |
| Maximum      | 150.00 |

Figure 2: Age Distribution for Users on Airbnb

Figure 4: Destination Choice based on Gender

### 3. PROPOSED ALGORITHMIC APPROACH

Using collaborative filtering to aggregate the similar users based on their first booking on Airbnb. The similarity between users is measured by cosine of the angle between the two vectors which indicate users' properties. Dimensionality reduction should be applied to reduce computational complexity and speed up the algorithm.
